DSC 1408 Representation Learning

Lecture 17 | Part 1

Least Squares Classifiers

Movie Ratings

- Five of your friends rate a movie from 0-10:
 - $X_1: 9$
 - $x_2: 3$
 - $x_3: 7$
 - $x_4: 2$
 - $x_5: 8$
- ► **Task**: Will you like the movie? (yes / no)

Classification

Linear prediction functions can be used in classification, too.

$$H(\vec{x}) = W_0 + W_1 X_1 + W_2 X_2 + ... + W_d X_d$$

Same ERM paradigm also useful.

A Classifier from a Regressor

- Binary classification can be thought of as regression where the targets are 1 and -1
 (or 0 and 1, or ...)
- $H(\vec{x})$ outputs a real number. Use the **sign** function to turn it into -1, 1:

$$sign(z) = \begin{cases} 1 & z > 0 \\ -1 & z < 0 \\ 0 & otherwise \end{cases}$$

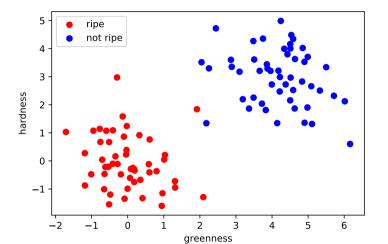

Final prediction: $sign(H(\vec{x}))$

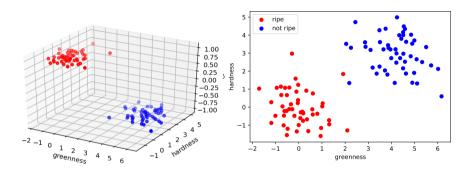

Example: Mango Ripeness

Predict whether a mango is ripe given greenness and hardness.

- Idea: gather a set of labeled training data.
 - Inputs along with correct output (i.e., "the answer").

Greenness	Hardness	Ripe
0.7	0.9	1
0.2	0.5	-1
0.3	0.1	-1
:	:	:

Decision Boundary

- The decision boundary is the place where the output of H(x) switches from "yes" to "no".
 - If $H > 0 \mapsto$ "yes" and $H < 0 \mapsto$ "no", the decision boundary is where H = 0.
- ► If H is a linear predictor and 1
 - $\vec{x} \in R^1$, then the decision boundary is just a number.
 - $\vec{x} \in \mathbb{R}^2$, the boundary is a straight line.
 - $\vec{x} \in \mathbb{R}^d$, the boundary is a d-1 dimensional (hyper) plane.

¹when plotted in the original feature coordinate space!

Empirical Risk Minimization

- Step 1: choose a hypothesis class
 - Let's assume we've chosen linear predictors
- ► Step 2: choose a loss function
- Step 3: minimize expected loss (empirical risk)

Exercise

Can we use the square loss for classification?

$$(H(\vec{x}^{(i)})-y_i)^2$$

Least Squares and Outliers

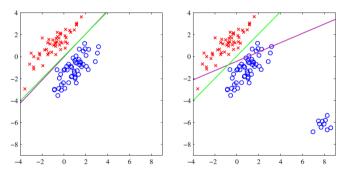

Figure 4.4 The left plot shows data from two classes, denoted by red crosses and blue circles, together with the decision boundary found by least squares (magenta curve) and also by the logistic regression model (green curve), which is discussed later in Section 4.3.2. The right-hand plot shows the corresponding results obtained when extra data points are added at the bottom left of the diagram, showing that least squares is highly sensitive to outliers, unlike logistic regression.

²Bishop, Pattern Recognition and Machine Learning

Square Loss for Classification

- ▶ We **can** use the square loss for classification
 - ► The "least squares classifier"
- However, the square loss penalizes being "too correct"

► **Example**: suppose the correct label is 1. What is the square loss of predicting 10? -9?

Loss Functions

There are many different loss functions for classification.

- Each leads to a different classifier:
 - Logistic Regression
 - Support Vector Machine
 - Perceptron
 - etc.

But that's for another class... (DSC 140A)

DSC 1408 Representation Learning

Lecture 17 | Part 2

Linear Limitations

Linear Predictors

Last time, we saw linear prediction functions:

$$H(\vec{x}; \vec{w}) = w_0 + w_1 x_1 + \dots + w_d x_d$$
$$= \operatorname{Aug}(\vec{x}) \cdot \vec{w}$$

Linear Decision Functions

- ► A linear prediction function *H* outputs a number.
- ▶ What if classes are +1 and -1?

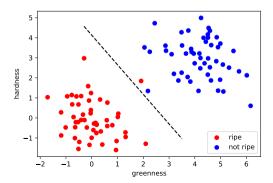

Can be turned into a decision function by taking:

$$sign(H(\vec{x}))$$

- Decision boundary is where H = 0
 - Where the sign switches from positive to negative.

Decision Boundaries

- A linear decision function's decision boundary is linear.
 - A line, plane, hyperplane, etc.

An Example: Parking Predictor

- ► **Task**: Predict (yes / no): Is there parking available at UCSD right now?
- What training data to collect? What features?

Useful Features

- ► Time of day?
- Day's high temperature?

...

Exercise

Imagine a scatter plot of the training data with the two features:

- x_1 = time of day
- x_2 = temperature

"yes" examples are green, "no" are red.

What does it look like?

Parking Data

Uh oh

- A linear decision function won't work.
- ► What do we do?

Today's Question

How do we learn non-linear patterns using linear prediction functions?

DSC 1408 Representation Learning

Lecture 17 | Part 3

Feature Maps

Representations

- We represented the data with two features: time and temperature
- In this **representation**, the trend is **nonlinear**.
 - ► There is no good linear decision function
 - Learning is "difficult".

Idea

- Idea: We'll make a new representation by creating new features from the old features.
- ► The "right" representation makes the problem easy again.
- What new features should we create?

New Feature Representation

- Linear prediction functions³ work well when relationship is linear
 - \triangleright When x is small we should predict -1
 - When x is large we should predict +1
- But parking's relationship with time is not linear:
 - ▶ When time is small we should predict +1
 - When time is medium we should predict -1
 - ► When time is large we should predict +1

³Remember: they are weighted votes.

Exercise

How can we "transform" the time of day x_1 to create a new feature x'_1 satisfying:

- ▶ When x'_1 is small, we should predict -1
- \triangleright When x'_1 is large, we should predict +1

What about the temperature, x_2 ?

Idea

- Transform "time" to "absolute time until/since Noon"
- Transform "temp." to "absolute difference between temp. and 72."

Basis Functions

- We will transform:
 - \triangleright the time, x_1 , to $|x_1 Noon|$
 - ► the temperature, x_2 , to $|x_2 72^{\circ}|$
- Formally, we've designed non-linear basis functions:

$$\varphi_1(x_1, x_2) = |x_1 - \text{Noon}|$$

$$\varphi_2(x_1, x_2) = |x_2 - 72^\circ|$$

▶ In general a basis function φ maps $\mathbb{R}^d \to \mathbb{R}$

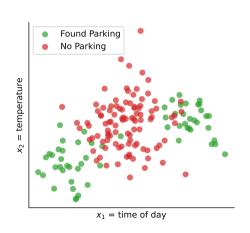

Feature Mapping

- ▶ Define $\vec{\varphi}(\vec{x}) = (\varphi_1(\vec{x}), \varphi_2(\vec{x}))^T$. $\vec{\varphi}$ is a **feature map**
 - ► Input: vector in "old" representation
 - Output: vector in "new" representation
- Example:

$$\vec{\phi}((10a.m., 75^{\circ})^{T}) = (2 \text{ hours, } 3^{\circ})^{T}$$

 $ightharpoonup \vec{\phi}$ maps raw data to a **feature space**.

Feature Space, Visualized

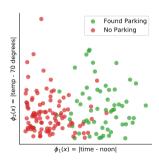

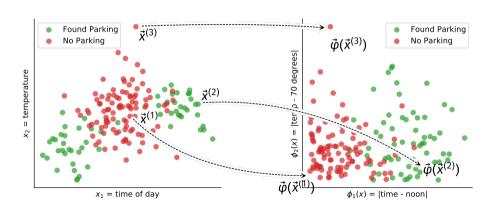

Exercise

Where does $\vec{\varphi}$ map $\vec{x}^{(1)}$, $\vec{x}^{(2)}$, and $\vec{x}^{(3)}$?

Solution

After the Mapping

The basis functions φ_1, φ_2 give us our "new" features.

- This gives us a new representation.
- In this representation, learning (classification) is easier.

Training

Map each training example $\vec{x}^{(i)}$ to feature space, creating new training data:

$$\vec{z}^{(1)} = \vec{\varphi}(\vec{x}^{(1)}), \quad \vec{z}^{(2)} = \vec{\varphi}(\vec{x}^{(2)}), \quad \dots, \quad \vec{z}^{(n)} = \vec{\varphi}(\vec{x}^{(n)})$$

Fit linear prediction function H in usual way:

$$H_f(\vec{z}) = W_0 + W_1 z_1 + W_2 z_2 + ... + W_d z_d$$

Training Data in Feature Space

Prediction

If we have \vec{z} in feature space, prediction is:

$$H_f(\vec{z}) = w_0 + w_1 z_1 + w_2 z_2 + \dots + w_d z_d$$

Prediction

But if we have \vec{x} from original space, we must "convert" \vec{x} to feature space first:

$$\begin{split} H(\vec{x}) &= H_f(\vec{\varphi}(\vec{x})) \\ &= H_f((\varphi_1(\vec{x}), \, \varphi_2(\vec{x}), \, ..., \, \varphi_d(\vec{x}))^T) \\ &= w_0 + w_1 \varphi_1(\vec{x}) + w_2 \varphi_2(\vec{x}) + ... + w_d \varphi_d(\vec{x}) \end{split}$$

Overview: Feature Mapping

A basis function can involve any/all of the original features:

$$\varphi_3(\vec{x}) = x_1 \cdot x_2$$

We can make more basis functions than original features:

$$\vec{\varphi}(\vec{x}) = (\varphi_1(\vec{x}), \varphi_2(\vec{x}), \varphi_3(\vec{x}))^T$$

Overview: Feature Mapping

- 1. Start with data in original space, \mathbb{R}^d .
- 2. Choose some basis functions, $\varphi_1, \varphi_2, ..., \varphi_{d'}$
- 3. Map each data point to **feature space** $\mathbb{R}^{d'}$: $\vec{x} \mapsto (\varphi_1(\vec{x}), \varphi_2(\vec{x}), ..., \varphi_{d'}(\vec{x}))^t$
- 4. Fit linear prediction function in new space:

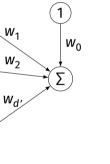

$$H(\vec{x}) = W_0 + W_1 \varphi_1(\vec{x}) + W_2 \varphi_2(\vec{x})$$

$$x_1$$
 φ_1 w_1 w_0 w_2 w_2 w_2 w_2 w_2 w_3

 $\varphi_{d'}$

 x_d

 $H(\vec{x}) = w_0 + w_1 \varphi_1(\vec{x}) + w_2 \varphi_2(\vec{x})$

Today's Question

- Q: How do we learn non-linear patterns using linear prediction functions?
- A: Use non-linear basis functions to map to a feature space.

DSC 1408 Representation Learning

Lecture 17 | Part 4

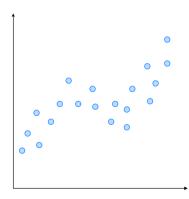

Basis Functions and Regression

By the way...

You've (probably) seen basis functions used before.

Linear regression for non-linear patterns in DSC 40A.

Example

Fitting Non-Linear Patterns

► Fit function of the form

$$H(x) = W_0 + W_1 x + W_2 x^2 + W_3 x^3 + W_4 x^4$$

Linear function of \vec{w} , non-linear function of x.

The Trick

- Treat x, x^2 , x^3 , x^4 as **new** features.
- Create design matrix:

$$X = \begin{pmatrix} 1 & x_1 & x_1^2 & x_1^3 & x_1^4 \\ 1 & x_2 & x_2^2 & x_2^3 & x_2^4 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 1 & x_n & x_n^2 & x_n^3 & x_n^4 \end{pmatrix}$$

- Solve $X^T X \vec{w} = X^T \vec{w}$ for \vec{w} , as usual.
- Works for more than just polynomials.

Another View

We have changed the representation of a point:

$$x \mapsto (x, x^2, x^3, x^4)$$

Basis functions:

$$\varphi_1(x) = x \quad \varphi_2(x) = x^2 \quad \varphi_3(x) = x^3 \quad \varphi_4(x) = x^4$$

DSC 1408 Representation Learning

Lecture 17 | Part 5

A Tale of Two Spaces

A Tale of Two Spaces

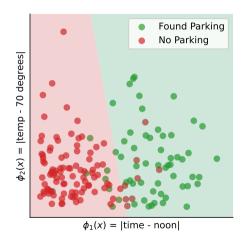

- ► The **original space**: where the raw data lies.
- The **feature space**: where the data lies after feature mapping $\vec{\phi}$
- Remember: we fit a linear prediction function in the **feature space**.

Exercise

- In **feature space**, what does the decision boundary look like?
- What does the prediction function surface look like?

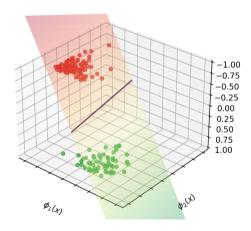

Decision Boundary in Feature Space⁴

⁴Fit by minimizing square loss

Prediction Surface in Feature Space

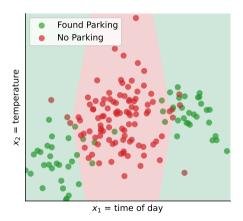

Exercise

- In the **original space**, what does the decision boundary look like?
- What does the prediction function surface look like?

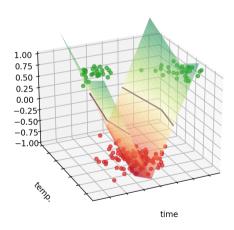

Decision Boundary in Original Space⁵

⁵Fit by minimizing square loss

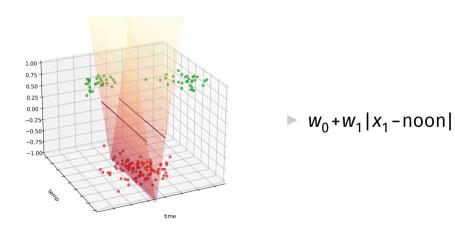

Prediction Surface in Original Space

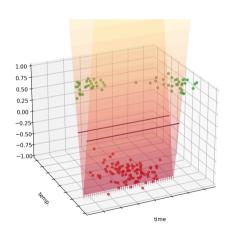

Insight

- \blacktriangleright *H* is a sum of basis functions, φ_1 and φ_2 .
 - $H(\vec{x}) = W_0 + W_1 \varphi_1(\vec{x}) + W_2 \varphi_2(\vec{x})$
- ► The prediction surface is a sum of other surfaces.
- Each basis function is a "building block".

Visualizing the Basis Function ϕ_1

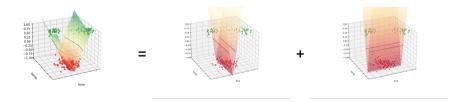

Visualizing the Basis Function ϕ_2

 $W_0 + W_2 | x_2 - 72^{\circ} |$

Visualizing the Prediction Surface

View: Function Approximation

Find a function that is ≈ 1 near green points and ≈ -1 near red points.

What's Wrong?

- We've discovered how to learn non-linear patterns using linear prediction functions.
 - Use non-linear basis functions to map to a feature space.
- Something should bug you, though...
